

FoxPro 3.0 is a relational database and development language that allows you to work with datasets and update them through Visual FoxPro's integrated development environment (IDE). If you've ever used Microsoft Access, then the GUI will look very familiar to you. The most important thing to know about Foxpro is that it uses a different data paradigm than an RDBMS such as MySQL or Postgres. It doesn't use tables like those systems do; instead, it has "records" which are parsed into fields with properties. This means that the order of fields does not matter; all of the information in each record is available whenever needed. This allows records to be re-ordered, and changed later on. Fields can even be added or deleted from existing records. FoxPro implements the common functionality of Microsoft Access in its own way, which means that it may or may not function with Access-based data. Foxpro also implements queries and queries results in a different way than the other programs do. It is very easy to get used to its way of doing things if you've used Microsoft Access before because the Visual FoxPro developers did a good job of implementing Access's functionality into their program. This keeps things simple and fast for experienced users while giving new users a recognizable GUI (Graphical User Interface) like the one they're used to. Foxpro uses the concept of "records" to store data - basically, they are similar to tables in Microsoft Access. Records can be manipulated as a whole, as well as individual fields within those records. However, you don't have the concept of primary key's and foreign key's as far as manipulating records goes. The reason for this is that it is much more flexible than using those concepts. Because there are no primary or foreign keys, you can do a lot more things to a record without needing to worry about the other pieces of the database. FoxPro uses a graphical database front-end called Visual FoxPro that allows you to build forms and other objects that implement your database functionality within your application. Visual FoxPro allows you to design complex database forms by using their own form designer. Forms can be given a title and displayed within the Foxpro IDE, and they can contain other forms and objects such as buttons and labels. The forms in Visual FoxPro are drawn in the same way that the software itself is drawn - with graphical lines, shapes, colors, etc. FoxPro was written by Brad Paisley who is known for writing music and vocalizing songs. He has one of the most popular voices in country music according to many polls taken by the country music profession's magazines which included Country Music Television (CMT) and Digital Music News (DNN). He is also known to have the most number of top ten songs in the history of country music. The song "Heaven South", which was written by Brad Paisley, was included in the album called "Time Well Wasted" that was released on September 5, 1997. To date, Brads Paisley's album has had more than 2 million copies sold all over the world. This puts him on top of the list of singers who sold more than 2 million copies for an album. He was born with perfect pitch.
